MACROECONOMIC ANALYSIS OF THE "TAX CUTS AND JOBS ACT" AS PASSED BY THE HOUSE OF REPRESENTATIVES ON NOVEMBER 16, 2017

Prepared by the Staff
of the
JOINT COMMITTEE ON TAXATION

December 11, 2017 JCX-66-17

INTRODUCTION

Pursuant to section 5107 of the Concurrent Resolution on the Budget for Fiscal Year 2018 and House Rule XIII(8)(b), this document, prepared by the staff of the Joint Committee on Taxation, provides an analysis of the macroeconomic effects of the "Tax Cuts and Jobs Act" as passed by the House of Representatives on November 16, 2017, and their impact on the Federal budget.

¹ This document may be cited as follows: Joint Committee on Taxation, *Macroeconomic Analysis of the* "Tax Cuts and Jobs Act" as passed by the House of Representatives on November 16, 2017 (JCX-66-17), December 11, 2017. This document can also be found on the Joint Committee on Taxation website at www.jct.gov.

MACROECONOMIC ANALYSIS OF THE "TAX CUTS AND JOBS ACT" AS PASSED BY THE HOUSE OF REPRESENTATIVES

This report provides an analysis of the macroeconomic effects of a proposal to reform the Internal Revenue Code ("Code"). Specifically, the proposal analyzed here is the one summarized in JCX-54-17, *Estimated Revenue Effects of H.R. 1, the "Tax Cuts and Jobs Act," as Reported by the Committee on Ways and Means on November 9, 2017*, November 11, 2017.² We estimate that this proposal would increase the level of output (as measured by real Gross Domestic Product ("GDP") by about 0.7 percent on average over the 10-year budget window. That increase in output would increase revenues, relative to the conventional estimate of a loss of \$1,436.8 billion by about \$483 billion over that period. This budget effect would be partially offset by an increase in interest payments on the Federal debt of about \$55 billion over the budget period. We expect that both an increase in GDP and resulting additional revenues would continue in the second decade after enactment, although at a lower level, as the incentive effects of several provisions that are expected to increase GDP within the budget window weaken over time.

The following discussion analyzes the macroeconomic effects of the bill. The estimate of the macroeconomic revenue feedback effects of this legislation and the following supplementary analysis were produced using three macroeconomic simulation models to simulate the growth effects of the bill: (1) the Joint Committee staff's Macroeconomic Equilibrium Growth ("MEG")³ model; (2) an overlapping generations model ("OLG");⁴ and (3) the Joint Committee staff's dynamic stochastic general equilibrium model ("DSGE").⁵ A brief description of the models and the parameter values for each used in this analysis appear in the Appendix to this document. This analysis is presented relative to the 2017 economic and receipts baseline ("present law") published by the Congressional budget Office ("CBO") in January, 2017.⁶

² The bill that was reported by the Committee on Ways and Means was unchanged when passed by the House of Representatives.

³ A detailed description of the MEG model may be found in Joint Committee on Taxation, *Macroeconomic Analysis of Various Proposals to Provide \$500 Billion in Tax Relief* (JCX-4-05), March 1, 2005, and Joint Committee on Taxation, *Overview of the Work of the Staff of the Joint Committee on Taxation to Model the Macroeconomic Effects of Proposes Tax Legislation to Comply with House Rule XIII3(h)(2)* (JCX-105-03), December 22, 2003.

⁴ The OLG model currently used by JCT is leased from Tax Policy Advisors, LLC. Information about this model may be found in John W. Diamond and George R. Zodrow, *Modeling U.S. and Foreign Multinationals in an OLG-CGE Model*, Baker Institute for Public Policy, Rice University, working paper, 2015; and in G.R. Zodrow and J.W. Diamond, "Dynamic Overlapping Generations Computable General Equilibrium Model and the Analysis of Tax Policy: the Diamond-Zodrow Model," in P.B. Dixon and D.W. Jorgenson (eds.) *Handbook of Computable General Equilibrium Modeling*, vol. 1A, pp. 743-813, North-Holland, 2013.

⁵ A description of an earlier version of the DSGE model may be found in Joint Committee on Taxation, Background Information about the Dynamic Stochastic General Equilibrium Model Used by the Staff of the Joint Committee on Taxation in the Macroeconomic Analysis of Tax Policy (JCX-52-06), December 14, 2006. An updated document, which describes modeling improvements, is forthcoming.

⁶ Congressional Budget Office, *The Budget and Economic Outlook: 2017-2027*, January 24, 2017.

Proposal

The bill changes individual income tax rates, reducing the number of individual income tax rate brackets from seven to four, with rates of 12 percent, 25 percent, 35 percent, and 39.6 percent, and phasing out the 12 percent bracket for taxpayers with taxable income above \$1 million (\$1.2 million for joint filers). The bill also changes the measure used to adjust the brackets for inflation from the present law consumer price index ("CPI-U") to the chained consumer price index ("chained CPI"). The chained CPI grows more slowly than the CPI-U, thus resulting in people over time moving into higher rate brackets at a faster rate under the bill than under present law. At the same time, the proposal eliminates a number of deductions and credits from individual taxable income while increasing others. The biggest changes include eliminating personal exemptions while increasing the standard deduction, repealing most itemized deductions (except for mortgage interest, investment interest, charitable contributions, and up to \$10,000 in real property taxes), repealing the alternative minimum tax on individual income, and increasing the maximum amount of the child tax credit while increasing the income range over which individuals may claim it, and adding a family credit. Finally, the bill generally doubles the exemption amount for the estate, gift, and generation skipping transfer tax, and repeals the estate and generation skipping transfer tax and reduces the gift tax rate after 2024.

The bill also makes substantial changes to the taxation of business income. It reduces the top tax rate on certain pass-through business income from 39.6 percent to 25 percent. In addition, the bill lowers the corporate income tax rate from 35 percent to 20 percent beginning in 2018 and repeals the alternative minimum tax on corporate income; and, it increases the rate of bonus depreciation to 100 percent while extending it for five years, from 2018 through 2022. The bill also repeals or limits deductions for a number of business expenses, the largest of which are a 30 percent limit on interest deductibility and denial of carryback treatment of the net operating loss deduction. Finally, the bill makes significant changes to the taxation of both foreign and domestically controlled multinational entities. It would allow domestic corporations to deduct 100 percent of dividends from their foreign subsidiaries, effectively switching the United States corporate tax from a worldwide to a territorial system. In order to reduce the erosion of the United States corporate income tax base, the bill adds a tax on high return earnings from controlled foreign corporations, reduces interest deductibility for multinational corporations, and imposes an excise tax on certain related party payments from United States business to foreign businesses. Taxpayers may elect to be subject to U.S. tax on their net income from these relatedparty payments instead of paying the excise tax.

Overall, the net effect of the changes to the individual income tax is to reduce average tax rate on total income by about 0.8 percentage points and on wage income by about 0.6 percentage points, while reducing effective marginal tax rates on wages by about 1.6 percentage points. The extension and expansion of bonus depreciation, and the reduction in tax rates on business income (both for corporations and for pass-through businesses) result in a reduction in the after-tax cost of capital investment, and thus an increase in the after-tax rate of return on business investment. This incentive begins to decline toward the end of the 10-year budget period because of the expiration of both 100 percent bonus depreciation, and because interest rates begin to rise as Federal debt increases due to the proposal.

Effects on output

We estimate that the proposal would increase the level of real GDP relative to the baseline forecast, by 0.7 percent on average throughout the 10-year budget window. In general, tax policy affects economic growth by changing incentives for owners of capital to invest and for potential workers to supply labor to the economy, and by changing the after-tax rates of return to these two factors of production. Changes in tax policy can alter these after-tax rates of return either directly by changing the amount of payments going to taxes, or indirectly, by changing aggregate demand, which can change gross payments for output. The projected increase in GDP during the budget window results both from an increase in labor supply, in response to the reduction in effective marginal tax rates on wages, and from an increase in investment in response to the reduction in the after-tax cost of capital. A gradual erosion of the reduction in marginal tax rates on wages due to the use of chained CPI to index rate brackets and the expiration of bonus depreciation are expected to slow the rate of growth toward the end of the budget window. As a result, the increase in output is expected to be smaller towards the end of the budget window.

Effects on capital stock

The amount of capital available for production is expected to be about 0.9 percent higher on average over the budget window than in the baseline forecast. During the budget window, increased investment in business capital is projected to arise from the reduction in the tax rates on corporate and certain pass-through business income, as well as from the five-year extension of bonus depreciation at 100 percent. This investment results in a gradual accumulation of capital stock, which is forecast to reach its peak sometime in the second half of the budget period. Somewhat offsetting this effect in the second half of the budget period is the effect of the growing deficit on interest rates, as well as the sunset of bonus depreciation.

Effects on employment and supply of labor

The reduction in marginal tax rates on labor (resulting primarily from lower statutory rates for significant portions of each tax bracket, and the expansion of the child credit) provides an incentive for an increase in labor supply. The reduction in the average and marginal tax rates on wages is enhanced in the first half of the budget window by an additional personal tax credit for each family member. This effect reverses after 2022 when that credit expires. Partially offsetting this incentive is the reduction in average tax rates on individuals, increasing their overall after-tax income for a given level of labor effort. Because the reduction in marginal tax rates is gradually reduced over the budget window, by the indexing of tax rate brackets to chained-CPI, the timing and strength of the labor supply response varies depending on how much foresight individuals are assumed to have about the future path of marginal tax rates. The more foresight individuals are assumed to have, the more they are forecast to shift their labor effort into the timeframe when marginal tax rates are relatively lower. On average, employment is projected to increase by about 0.5 percent relative to baseline levels during the budget period, with more of that increase occurring in the first half of the budget window.

Effects on consumption

The additional income generated by additional capital and labor - combined with the decreased tax liability owing to the proposal - provide individuals with more disposable income, thus increasing consumption. We estimate that consumption would be increased by 0.5 percent on average during the budget window, relative to baseline levels of consumption.

Effects of changes to the estate, gift, and generation skipping transfer tax

Evidence from economic empirical and theoretical research on the effects of the estate, gift, and generation skipping transfer taxes (referred to here as "estate tax") on economic growth are very mixed. On the one hand, to the extent that an individual's labor effort and investment behavior is driven by a desire to maximize the amount of wealth to be left to heirs, the increased exemption from and ultimate repeal of the estate tax would increase the marginal value to him of providing these additional resources to the economy; if this were the only behavioral response to the estate tax, the provision would be expected to increase growth. However, it is also possible that individuals subject to the estate tax desire to leave a specific dollar amount to their heirs; in this case, the reduction and eventual repeal of the tax would allow them to reach that target amount more quickly, thus reducing their incentive to work and invest. In addition, to the extent that the reduction and eventual repeal of the estate tax increases the amount of income received by heirs, this could reduce the labor supply and savings of the heirs, thus reducing the amount of growth in the economy. Because of the uncertainty associated with the effects of the estate tax on growth from labor and investment incentives, the changes to the estate tax are incorporated in JCT macro models as a reduction in the average tax rate on individual income, and as having no effect on marginal tax rates, which are the main drivers of behavioral response in JCT macroeconomic models. Thus, the effects of the estate tax reduction and repeal are primarily a small increase in consumption, and a negligible change in GDP and other macroeconomic aggregates.⁷

Effects of changes in the treatment of income from foreign activity

The proposal changes the taxation of both foreign and domestically controlled multinational corporations in order to switch the foreign tax regime from a worldwide to a territorial basis, and to limit erosion of the corporate income tax base.

To some extent, under present law, base erosion occurs because firms are able to attribute their profits to low-tax countries and their costs to the United States without changing the location of their economic activity. The proposals affecting taxation of foreign activity are expected to reduce the incentives for this "profit-shifting" activity, thus resulting in an increase in the U.S. tax base. The conventional revenue estimates for these provisions include the effects of reducing profit shifting. The effects of these types of provisions on incentives to locate economic activity in the United States are included in the macroeconomic analysis and feedback

⁷ For a brief discussion on ramifications of estate taxation, see Joint Committee on Taxation, *The Taxation of Individuals and Families* (JCX-41-17), September 12, 2017, pp. 47-48, and for additional data and a more detailed discussion of economic issues, see Joint Committee on Taxation, *History, Present Law, and Analysis of the Federal Wealth Transfer Tax System* (JCX-52-15), March 16, 2015, pp. 24-46.

estimate. The macroeconomic estimate projects an increase in investment in the United States, both as a result of the proposals directly affecting taxation of foreign source income of U.S. multi-national corporations, and from the reduction in the after-tax cost of capital in the United States due to more general reductions in taxes on business income.

Budgetary effects

Fiscal years 2018-2027

The estimate of the impact of the growth effects from this proposal on its overall budget effects was produced using a weighted average of those effects generated by the MEG, OLG, and DSGE models. The OLG and MEG models are each assigned a weight of 0.4, while DSGE is assigned a weight of 0.2. As described in the Appendix, each model provides a somewhat different perspective on savings/investment responses and international capital flows. The OLG model provides some focus on shifting of investment between domestic and multinational corporations, as well as within multinational corporations across borders, but requires a fiscal balance assumption. The MEG model allows simulation of the proposal as drafted, with no offsetting fiscal balance assumption, and it models cross-border capital flows that can partially offset the effects of a growing deficit on interest rates. The DSGE model is included because, although it does not model cross-border flows, it does model separate investment responses by savers and non-savers. It also adds imperfect foresight to the analysis, an assumption sitting between the perfect foresight assumption of the OLG model and the myopic foresight in the MEG model. The foresight assumption is particularly important for analyzing the effects of provisions and incentives that change over time. The growth generated by the proposal is projected to reduce the revenue loss from the proposal by about \$483 billion over the 2018-2027 budget period. At the same time, an increase in interest rates generated by the increase in Federal debt is expected to increase the cost of Federal debt service by about \$55 billion over the budget window. Overall, the budgetary effects of changes in economic growth are projected to reduce the deficit by \$428 billion during the budget window. Details of the estimate appear on Table 1, on page 8.

Second and third decade effects

In the second decade after enactment, the direct tax incentives for increased labor effort that contributed to the projected increase in GDP during the ten-year budget window are reduced, with the continuing effect generated by indexing tax brackets by chained CPI of moving people to higher tax brackets more quickly than they would be moved under present law. The increased revenues due to chained CPI slow the growth of the deficit in the second and third decades. The chained CPI provision results in an increasing marginal tax rate on labor over time, relative to the first ten years of the proposal, dampening labor supply incentives, and reducing the increase in GDP relative to projected baseline levels. Given other changes to individual tax rates that are also part of the proposal, it is uncertain whether this increase over time will result in marginal tax rates that are higher under the proposal than under present law by the end of the third decade. The permanent reduction in the corporate income tax rate continues to provide an incentive for increased investment and GDP in the second decade, but the increase in debt generated by the proposal is expected to continue to exert some upward pressure on interest rates, partially or wholly offsetting investment incentives by the end of the third decade. Because

of competing incentive effects over time, it is uncertain whether GDP and possible revenue feedback will continue to be higher than under present law by that time.

APPENDIX: DATA, MODELS, AND ASSUMPTIONS USED IN THE ANALYSIS

The Joint Committee staff analyzed the proposal using the Joint Committee staff MEG and DSGE models and an OLG model. While the models are based on economic data from the National Income and Product Accounts, taxable income is adjusted to reflect taxable income as measured by reporting on tax returns. All three models start with the standard, neoclassical production framework in which the amount of output is determined by the quantity of labor and capital used by firms, and the productivity of those factors of production; long run aggregate demand equals aggregate supply at full employment. Both individuals and firms are assumed to make decisions based on observed characteristics of the economy, including wages, prices, interest rates, tax rates, and government spending levels. In particular, the amount of labor available to the economy is affected by individuals' understanding of their after-tax returns to working, which depends on both wage rates and tax rates. Similarly, the amount of capital available to the economy is determined by investors' predictions of after-tax returns to capital, which depend on anticipated gross receipts, costs of factor inputs, and tax rates that affect those factors. The underlying structure of the MEG model relies more on reduced form behavioral response equations, while the OLG and DSGE models incorporate more theoretical microeconomic foundations.

The degree to which the Joint Committee staff relies more heavily on the results of one model versus the others depends on the specifics of the proposal being analyzed. The MEG model, which does not require a fiscal balance assumption, is better suited to analyze proposals that produce large, conventionally estimated deficits. This model allows for the modeling of four separate types of labor, and of separate marginal and average tax rates for all major individual and business income tax sources; while the other two models treat average and marginal rates the same for individual income other than wages. The availability of investment capital to firms is determined by individuals' savings response to changes in the after-tax rate of return on investment as well as by foreign capital flows. Also in the MEG and DSGE models, monetary policy conducted by the Federal Reserve Board is explicitly modeled, with delayed price adjustments to changes in economic conditions allowing for the economy to be temporarily out of equilibrium in response to fiscal and monetary policy. The monetary policy response function used in this analysis assumes that the Fed will act to counteract demand stimulus resulting from the proposal because the economy is expected to be operating near full employment. The myopic expectation framework in the MEG model represents the extreme case of the degree of foresight individuals have about future economic conditions, in which individuals assume in each period that current economic conditions will persist permanently.

At the other end of the foresight spectrum, in the OLG model, individuals are assumed to make consumption and labor supply decisions to maximize their lifetime well-being given the resources they can foresee will be available to them. They are assumed to have complete information, or "perfect foresight," about economic conditions, such as wages, prices, interest rates, tax rates, and government spending, over their lifetimes. OLG represents a class of models with "micro-foundations" and life-cycle effects modeled separately for each of a number of "generations" (in this case 55). Taxes on labor affect the decisions of each cohort by impacting the trade-off between consumption and leisure. Individuals substitute between labor and leisure both contemporaneously and over time. The OLG model includes a more differentiated business sector than the other two models, separately modeling responses of non-corporate businesses,

domestic corporations, and multi-national corporations and their subsidiaries. Firms' investment decisions respond to the effects of tax policy on the projected future value of the firm. Changes in marginal tax rates on firm profits, and changes in the value of deductions for investment affect this future valuation.

The stochastic feature of the DSGE model allows for some analysis of the effects of uncertainty about future fiscal policy on the modeling outcome, representing a less extreme foresight assumption than either of the other models. As the uncertainty about future fiscal conditions is allowed to persist over a limited period of time, DSGE is closer to OLG than to MEG on this spectrum. In DSGE there are two types of individuals who make decisions about labor supply, only one of whom has the liquidity to make investment decisions ("savers and non-savers"). As in the OLG model, these two types of individuals make consumption and labor supply decisions to maximize their discounted present value of consumption over time, including consumption of leisure. The savers supply investment capital to the economy, and receive income from investment returns. The non-savers are liquidity constrained, and are unable to invest. The existence of these two types of individuals allows for some explicit distributional analysis of taxes on investment versus taxes on labor. In addition, changes to transfers and taxes on the non-saving households will have direct effects on current period consumption and the current level of output. These features of the DSGE model allow the model to interpret real short run effects of economic policy changes.

In the OLG and DSGE models, the ability of individuals to foresee changes in fiscal conditions means that the agents in the models will be unable to make optimal economic decisions if they can foresee a permanently unstable economic future, thus preventing the models from "solving" – or completing their simulations. This problem arises in a situation where deficits are expected to increase faster than the rate of growth of GDP, which is a characteristic under present law as well as the bill. Thus, it is necessary to make counter-factual "fiscal balance" assumptions about the expected path of deficits for these models.

In the baseline, the OLG model maintains a constant debt to GDP ratio primarily by reducing government purchases. For the proposal analyzed in this document, which is expected to increase the debt to GDP ratio over time, the OLG model simulates the policy as stipulated for 30 years, and adjusts transfer payments thereafter to stabilize the debt to GDP ratio.

Decision-makers in the DSGE model are able to foresee the consequences of the new policy in the bill with certainty for the first 2.5 years of the budget window. Each quarter after that, they assume there is some probability (which increases over time) that the debt-to-GDP ratio will stabilize, thus allowing the model to solve and the simulation to continue. At the same time, the actual policy is implemented through a series of shocks throughout the 10-year budget period. After 10 years, the model assumes the debt-to-GDP ratio returns to a steady state.

The 30-year delay in imposing fiscal balance in OLG, and the uncertain expectations with respect to future fiscal conditions in DSGE, reduce the impact of the models' respective fiscal balance assumptions on decisions made inside the budget window.

Information about the effects of the proposal on individual and business average tax rates and effective marginal tax rates, and on after-tax returns to capital and labor is obtained from

various Joint Committee staff tax models⁸ (used in the production of conventional revenue estimates) to characterize the effects of the bill within the each of the models. Changes in deductions, credits and exclusions can impact effective marginal tax rates as well as average tax rates. Tables 2-4 provide a summary of key behavioral parameters used in the each of the models for the analysis of this proposal.

Table 2: Key Parameter Assumptions in the MEG Model

Labor supply elasticities in disaggregated labor supply	Income	Substitution
